

ITT Inc. Technology and Investment

Baseline Report

SECTION 1 — Quantitative investment baseline

Uploaded-document evidence:

The uploaded annual report and financial statements for the fiscal year ended December 31, 2025, provide an exhaustive overview of ITT Inc.'s financial positioning, capital allocation strategies, and investment intensity across its global operations. The company reported total consolidated revenue of \$3,938.5 million in 2025, representing an 8.5 percent year-over-year increase from the \$3,630.7 million recorded in 2024, and a 20.0 percent increase from the \$3,283.0 million recorded in 2023.¹ The company attributes this revenue expansion to strong execution, share gains, and a combination of organic growth and strategic acquisitions.¹ The company operates through three primary segments, each exhibiting distinct financial profiles and investment needs. The Industrial Process (IP) segment, which manufactures engineered fluid process equipment, pumps, and valves, generated \$1,496.2 million in 2025, a 9.9 percent increase from 2024.¹ The Motion Technologies (MT) segment, which produces brake components and shock absorbers, generated \$1,428.2 million in 2025, a slight decrease of 1.4 percent year-over-year.¹ This nominal decrease was heavily influenced by the strategic divestiture of the Wolverine Advanced Materials business in July 2024; excluding this divestiture and foreign currency impacts, the MT segment achieved organic revenue growth of 1.9 percent.¹ The Connect & Control Technologies (CCT) segment, focusing on harsh-environment connectors and aerospace components, generated \$1,017.0 million in 2025, a robust 23.3 percent increase driven significantly by the integration of newly acquired businesses.¹

Segment	2025 Revenue (\$M)	2024 Revenue (\$M)	2023 Revenue (\$M)	Year-over-Year Change (2024-2025)
Industrial Process (IP)	\$1,496.2	\$1,361.0	\$1,129.6	+9.9%
Motion Technologies (MT)	\$1,428.2	\$1,447.8	\$1,457.8	-1.4%
Connect & Control Technologies	\$1,017.0	\$825.1	\$699.4	+23.3%

(CCT)				
Eliminations	\$(2.9)	\$(3.2)	\$(3.8)	N/A
Total Consolidated Revenue	\$3,938.5	\$3,630.7	\$3,283.0	+8.5%

The company's gross profit for 2025 was \$1,392.4 million, reflecting a gross margin of 35.4 percent, which represents a 100-basis-point expansion from the 34.4 percent gross margin recorded in 2024.¹ Operating income for 2025 stood at \$684.5 million, a 0.9 percent increase from the \$678.1 million recorded in the prior year.¹ The financial filings note that operating margin experienced a slight contraction to 17.4 percent in 2025, down 130 basis points from 18.7 percent in 2024.¹

To sustain its technological competitiveness and product innovation, ITT maintains steady capital allocation toward research and development (R&D) and engineering expenses. R&D expenses were reported at \$110.8 million for 2025, representing a 4.7 percent decrease from the \$116.3 million expended in 2024, and an increase from the \$102.6 million spent in 2023.¹ The annual report attributes the year-over-year decrease in R&D primarily to the divestiture of the Wolverine business and the completion of certain specific R&D projects during the 2025 fiscal year.¹ As a percentage of total sales, R&D expenses accounted for approximately 2.8 percent in 2025, down from 3.2 percent in 2024 and 3.1 percent in 2023.¹ The company states that its R&D is heavily focused on the design of highly engineered critical components that operate in harsh environments, including the development of variable-speed motors and low-emission braking technologies.¹

Capital expenditures (capex) reflect a sustained commitment to funding future growth through capacity expansion, productivity improvements, and innovation. For the second consecutive year, capex exceeded \$120 million, coming in at \$121.3 million for 2025, compared to \$123.9 million in 2024 and \$107.6 million in 2023.¹

Segment	2025 Capex (\$M)	2024 Capex (\$M)	2023 Capex (\$M)
Motion Technologies	\$75.0	\$75.3	\$72.0
Industrial Process	\$24.5	\$34.2	\$17.7
Connect & Control	\$19.9	\$13.1	\$16.1

Technologies			
Corporate and Other	\$1.9	\$1.3	\$1.8
Total Capital Expenditures	\$121.3	\$123.9	\$107.6

Regarding software and digital infrastructure, the financial statements outline the company's accounting policies for capitalized internal-use software. The company expenses costs incurred in the preliminary project stage of developing or acquiring internal-use software. Once a project is approved and deemed probable for completion, ITT capitalizes certain internal and external costs related to software coding, designing system interfaces, installation, and testing.¹ These capitalized costs are amortized using the straight-line method over an estimated useful life of three to seven years.¹ As of December 31, 2025, the company disclosed a net balance for capitalized software costs of \$4.6 million, a slight decrease from the \$5.5 million recorded at the end of 2024.¹ The relatively low balance of capitalized software assets relative to the company's total asset base of \$6,310.4 million suggests that the bulk of ITT's technology expenditures are either treated as operating expenses (such as cloud subscriptions and SaaS licenses) or embedded within broader manufacturing and engineering line items rather than capitalized as discrete software assets.

The annual report notes that the company is undertaking multi-year implementations of new enterprise business systems at many of its sites, including within its shared services subsidiary.¹ The filing acknowledges that these implementations require significant capital investment and human resources, though it does not isolate the exact financial figures dedicated to these enterprise resource planning (ERP) systems.¹ The company also operates a 24/7/365 managed security operations center (SOC) to monitor its IT environment, which incorporates agentic-AI capabilities and artificial intelligence-based threat detection technology.¹

Investment intensity at ITT is heavily skewed toward inorganic growth through large-scale acquisitions that reshape the portfolio toward high-growth end markets. In December 2025, ITT entered into a definitive agreement to acquire SPX FLOW, a leading provider of pumps, valves, mixers, and aftermarket services, for an aggregate purchase price of approximately \$4,775 million.¹ This transaction is structured to be funded with \$4,075 million in cash and 3,839,824 shares of ITT common stock.¹ To finance the cash portion, the company issued 8.05 million shares of common stock in December 2025, generating net proceeds of \$1,314.1 million, and secured commitments for a \$2,875 million term loan facility.¹ The acquisition is expected to add approximately 3,800 employees and significantly expand the Industrial Process segment's capabilities in food, beverage, personal care, and chemical markets.¹

Prior to the SPX FLOW announcement, the company completed two significant acquisitions in

2024. In January 2024, ITT acquired Svanehoj Group A/S for a purchase price of \$407.6 million (net of cash acquired) to expand its cryogenic pump portfolio for the marine sector.¹ In September 2024, the company acquired kSARIA Parent, Inc. for \$460.1 million (net of cash acquired) to enhance its mission-critical connectivity solutions for defense and aerospace markets.¹ Restructuring costs associated with optimizing the cost structure and integrating these acquired businesses amounted to \$21.3 million in 2025, up from \$8.1 million in 2024.¹ The financial filings explicitly discuss several macroeconomic factors influencing the company's operational and technological investments. Management highlights that the manufacturing industry is experiencing a skilled labor shortage, making talent retention and acquisition difficult.¹ This shortage drives the necessity for targeted automation and digital transformation.¹ The company also notes that the integration of artificial intelligence (AI), including generative AI (GenAI), into engineering and manufacturing processes amplifies cybersecurity risks, prompting the creation of a GenAI Governance Committee to oversee tool deployment.¹ The annual report does not disclose discrete revenue figures for software, data platforms, or connected services, indicating that digital revenues are embedded within the hardware sales of the respective segments.

Public-source evidence:

Public evidence aligns with the financial filings and provides limited additional quantification of facility-level technological investments. In 2023, ITT announced an initial 50 million Euro investment to expand its Friction production facility in Termoli, Italy, and upgrade its R&D capabilities in Barge, Italy.² This investment includes funding for fast prototyping, expanded testing machinery, and an automated production module specifically designed to handle the demanding specifications of high-performance brake pads for luxury and sporting vehicles.² Public statements indicate that this total investment could grow to approximately 70 million Euros based on additional brake pad platform awards.²

The company also leverages government assistance and regional funds to support its capital and technological investments. During the year ended December 31, 2025, ITT received a capital-related grant of \$7.9 million from the Italian government associated with the expansion of the Termoli and Barge facilities.¹ Additionally, the highly innovative ITT Smart Pad brake pad project was supported by funding from "POR FESR Piemonte 2014-2020," a regional fund in Italy designed to sponsor projects moving from basic research into industrial environments and marketable products.⁵

Trade publications and industry analysis highlight that ITT is executing a robust digital growth strategy aimed at transforming its traditional industrial manufacturing base into a technology-driven enterprise with higher-margin, recurring revenue streams.⁶ Products such as the VIDAR smart motor are identified as targeting a new \$6 billion market segment, expanding the company's footprint through software-as-a-service (SaaS) offerings and intelligent hardware.⁷ However, public financial disclosures and trade reports do not disaggregate the specific revenue generated purely from digital services or SaaS subscriptions.

Assessment:

The quantitative evidence demonstrates that ITT's absolute investment intensity is

predominantly focused on large-scale hardware and manufacturing acquisitions, as evidenced by the pending \$4.775 billion SPX FLOW transaction and the nearly \$900 million deployed for the kSARIA and Svanehoj acquisitions. Organic investments in R&D and capital expenditures remain stable and robust at approximately \$110 million and \$121 million, respectively. The explicitly disclosed capitalized internal-use software balance of \$4.6 million is notably low for a multinational enterprise generating nearly \$4 billion in revenue. This suggests that the company likely expenses many of its software development costs as incurred, relies heavily on cloud-based operational expenditures (SaaS licenses), or embeds its software engineering costs within broader R&D and manufacturing line items. The lack of explicitly disclosed, standalone AI-specific or data-specific capital expenditure lines in the financial filings indicates that digital technologies are treated as enabling components for traditional flow and friction products rather than independent commercial software segments. The evidence supports a conclusion that the company is funding targeted digital integration into physical assets (such as smart motors and automated production modules) and investing heavily in enterprise IT modernization, but it does not support a conclusion of massive internal capital allocation toward proprietary foundation model training or standalone commercial software engineering.

SECTION 2 — Capability-by-capability analysis, including GenAI and agentic systems

Based on the uploaded hiring dataset and public evidence, ITT is investing in several distinct capability pockets across its enterprise operations and product portfolios. The following subsections reconstruct these investments, focusing on practical applications, engineering mechanisms, and evidence-calibrated maturity levels.

Machine learning and predictive modeling for materials science and friction R&D

Uploaded-document evidence:

The uploaded hiring dataset quantifies hiring signals within the "Materials Research" business area, specifically tracking three observed postings for AI-core roles.¹ The hiring data indicates that the company is seeking capabilities related to machine learning and data analysis tools to support product development and internal innovation projects.¹ The dataset explicitly links these roles to data collection and analysis designed to accelerate the development of new digital solutions and internal tools.¹ The dataset does not provide evidence that these models are deployed in commercial software products, nor does it quantify the operational impact of these research hires on the factory floor.

Public-source evidence:

Public evidence extensively details the specific scientific and engineering applications of these materials research capabilities. ITT operates a collaborative academic-industrial partnership known as the UniTO-ITT Joint Lab, located in Turin and at the company's Friction Technologies headquarters in Barge, Italy.⁸ Through this Joint Lab, researchers apply machine learning methods coupled with rigorous experimental design to optimize the synthesis of advanced materials used in friction applications, specifically titanium dioxide (TiO₂) and strontium titanate

nanoparticles.⁸

The engineering problem being solved is the precise control of nanoparticle morphology—specifically size, polydispersity, and aspect ratio—during hydrothermal synthesis processes.⁸ The machine learning models developed at the Joint Lab are trained to predict synthesis outcomes based on process parameters (such as pH values and temperatures) with high accuracy.⁸ Furthermore, researchers utilize a reverse-engineering approach, deploying the machine learning models to determine the optimal synthesis parameters required to achieve a specific, pre-defined product characteristic, allowing for continuous and precise control of nanoparticle morphology.⁸ The Joint Lab is also researching the application of artificial intelligence for the automated and reliable identification and size analysis of nanoplatelets using electron microscopy images.¹⁰

Beyond chemical synthesis, the company is exploring the use of AI in its physical brake pad testing processes.¹² By leveraging a massive historical database of testing results compiled over decades of R&D at the Barge innovation center, the company aims to simulate testing digitally.¹² The operational and strategic problem solved by this capability is the high cost and environmental impact of physical automotive testing; digital simulation helps reduce the fuel consumed by test vehicles and minimizes the release of brake pad particulate matter.¹²

The practical outputs of this advanced R&D include the "Geo-Pad," a copper-free, low-steel brake pad utilizing recycled ceramic fibers, which is currently in trials with a major European OEM for a 2028 start of production (SOP).¹³ Additionally, the company has developed the ITT Smart Pad, an intelligent friction component featuring sensors embedded on the backplate that actively measure temperature, pressure distribution, torque, residual torque, vibration, noise, and wear.⁵ This telemetry data is fed in real-time to the vehicle's braking and telematics systems to support anti-lock braking systems, electronic stability control, and autonomous emergency braking.⁵

Assessment:

The evidence supports internal pilot activity and capability building for machine learning in computational materials science, coupled with production deployment of sensor-embedded smart hardware (the ITT Smart Pad). The company is actively utilizing predictive modeling to accelerate the synthesis of friction materials and reduce the physical overhead of brake pad testing. Because this predictive ML capability is heavily concentrated within an academic partnership (the UniTO-ITT Joint Lab) and experimental research frameworks, it represents internal R&D capability rather than a scaled commercial digital product. The evidence suggests that the practical business effect of this investment is a reduction in R&D cycle times, lower physical prototyping costs, and the accelerated market entry of environmentally compliant, high-performance friction materials.

Generative AI, RAG, and agentic systems for enterprise quoting and product configuration (ePrism)

Uploaded-document evidence:

The uploaded hiring dataset reveals the highest concentration of AI-core roles within the "IT

and Data" business area, accounting for nine observed postings.¹ These roles encompass both AI/ML modeling (six postings) and LLM/GenAI applications (three postings).¹ The hiring dataset indicates that the company is investing in LLM workflows, Retrieval-Augmented Generation (RAG) architectures, and AI agents to automate business operations, streamline processes across the value chain, and extract document data.¹ The dataset also reveals a distinct geographical concentration of AI hiring in Greece, which accounted for seven AI-core postings (representing 6.7 percent of the total postings in that country).¹

Public-source evidence:

Public evidence connects the Greek hiring signals to a specific commercial software development operation. ITT operates a "Tech Hub" in Athens, Greece, employing over 80 professionals dedicated to custom software and web application development for the global enterprise.¹⁸ The primary product developed and maintained by this hub is "ePrism," an internal software solution utilized by the Industrial Process segment for product selection, configuration, and quotation (CPQ).¹⁸ ePrism serves as a web-based application that allows internal sales teams and external distributors (such as those selling Goulds Pumps and Engineered Valves) to generate proposals, request lead times, check order status, manage documents, and execute workflow automation.¹⁸

The engineering architecture of the ePrism platform relies on a monolithic Java 17 backend, a React v18 frontend, SQL Server databases, RabbitMQ for messaging, and GitLab for CI/CD.¹⁸ To augment this platform with advanced intelligence, the company is actively recruiting Senior AI/ML Engineers in Athens to design and implement generative AI capabilities.²²

The job specifications for these engineering roles reveal the exact technology stack and workflows involved. Engineers are tasked with designing and implementing LLM, RAG, AI agent, and automation solutions utilizing Microsoft Azure, Microsoft Fabric, Azure AI services, Azure OpenAI, and Copilot Studio.²² The target workflow for these GenAI integrations involves collaborating with business and IT stakeholders to identify operational pain points, extract data from complex documents, and create automated enterprise workflows that reduce the manual administrative burden of the sales and configuration process.²²

Assessment:

The evidence supports internal capability building and pilot activity for GenAI, RAG, and agentic systems within the company's CPQ and sales operations workflows. The company is developing these capabilities internally utilizing its Athens Tech Hub engineering talent rather than relying solely on off-the-shelf SaaS configuration platforms. The practical business effect of integrating Azure OpenAI and RAG architectures into the ePrism stack is the automation of highly complex, document-heavy industrial quoting and product configuration processes, allowing sales engineers to generate proposals faster and with greater accuracy. While the evidence confirms the intent to deploy Microsoft-backed GenAI tools within this workflow, public evidence does not yet confirm that these specific GenAI and agentic features have reached scaled production deployment across the entire global distributor network.

Vendor-supported automated diagnostics and machine health

monitoring (i-ALERT)

Uploaded-document evidence:

The uploaded hiring dataset shows two observed AI-core postings within the "Manufacturing Operations" business area.¹ The dataset summarizes that the company is directing AI and machine learning toward real-time monitoring to improve manufacturing operations.¹ The dataset does not provide evidence that the company is building proprietary foundational diagnostic algorithms internally for commercial sale.

Public-source evidence:

Public evidence demonstrates that the company's primary commercial offering in machine health monitoring relies on a mature vendor partnership. ITT manufactures the i-ALERT condition-based monitoring solution, an Industrial Internet of Things (IIoT) ecosystem used to monitor rotating equipment such as pumps and motors across the oil and gas, chemical, and power generation industries.²⁴ The hardware component, the i-ALERT3 sensor, acts as an edge computing device that measures tri-axial vibration, tri-axial kurtosis, temperature, and pressure, transmitting data via Bluetooth 5.0 to a gateway.²⁴

The data collected at the edge is processed in the cloud via the i-ALERT Ai Platform, a web interface that provides automated machine health diagnostics.²⁴ The engineering and analytical problem solved by this system is the early detection of mechanical and electrical failures, allowing plant managers to transition from reactive maintenance to proactive condition-based monitoring, thereby reducing unplanned industrial downtime.²⁴

However, the predictive intelligence and machine learning capabilities driving these diagnostics are not proprietary to ITT. Public press releases and trade reports confirm that fault detection and actionable recommendations occur through proprietary algorithms developed by ITT's asset health partner, Symphony AzimaAI (now SymphonyAI).²⁵ Symphony AzimaAI provides the sophisticated rules-based methodology and predictive insights that translate raw vibration and temperature data into specific fault diagnoses and maintenance recommendations.²⁵

Assessment:

The evidence supports vendor-supported commercial deployment of AI and machine learning for predictive maintenance. ITT successfully manufactures and distributes the physical edge hardware (sensors and gateways) and provides the web-based management interface, but it integrates third-party algorithms (from Symphony AzimaAI) to execute the actual machine learning analysis and fault detection. This implies that the company leverages mature vendor ecosystems to provide advanced digital capabilities to its customers, avoiding the heavy R&D costs and data science headcount associated with building and maintaining proprietary predictive maintenance algorithms from scratch.

Embedded software and variable-speed intelligence for fluid control (VIDAR and PumpSmart)

Uploaded-document evidence:

The annual report identifies VIDAR as a next-generation embedded motor drive platform

launched by the company.¹ The filing states that VIDAR is a state-of-the-art variable-speed motor that eliminates the need for mechanical controls, reduces energy consumption and carbon dioxide output, and ensures that flow controls are more precise.¹ The uploaded documents do not detail the specific software architecture or logic controllers used within this system.

Public-source evidence:

Public evidence details how ITT embeds software into its heavy industrial equipment to solve operational efficiency problems. The VIDAR motor integrates variable-speed intelligence directly into the motor technology, bypassing the need for external variable frequency drives (VFDs) or complex wiring arrays.³⁰ The system includes built-in connectivity that enables remote diagnostics and remote software updates, shifting the maintenance workflow from reactive on-site visits by technicians to proactive remote support.³³

Similarly, the company's PumpSmart system relies on embedded software to protect pumps and optimize flow without the need for external sensors.³⁴ PumpSmart utilizes a standard variable frequency drive—specifically partnering with ABB for the hardware (e.g., the ABB ACS880)—and embeds ITT Goulds Pumps' proprietary pump-specific control algorithms directly onto the drive.³⁴ The software calculates flow and pressure internally, providing sensorless protection against common failure modes such as dead-heading, cavitation, dry running, and run-out conditions.³⁵ The system also utilizes Integrated Process Control (PID) algorithms to provide automatic pump and set-point control, linking multiple pumps together.³⁴

Assessment:

The evidence supports production deployment of embedded control software and digital intelligence in industrial hardware. The company is actively building and deploying proprietary control logic (as seen in the PumpSmart algorithms) while leveraging established hardware vendors (like ABB) to deliver the physical drive infrastructure. The business problem solved is energy inefficiency, mechanical failure in harsh environments, and the complexity of external sensor wiring. The evidence indicates that the company's digital strategy heavily emphasizes edge computing and embedded logic that directly controls physical fluid dynamics, representing a highly mature and commercialized application of digital technology.

Cloud-based Quality Management Systems (QMS) for manufacturing compliance

Uploaded-document evidence:

The annual report states that the company applies a continuous improvement mindset and an "Accept Only Zero" safety accountability system across its manufacturing facilities to raise performance standards and serve customers better.¹ The filing also notes that the company is engaged in multi-year implementations of new enterprise business systems at many sites to improve the efficiency and effectiveness of critical value-chain processes.¹ The uploaded hiring report indicates that AI and machine learning are being directed toward real-time monitoring and quality control to ensure product standards in manufacturing.¹

Public-source evidence:

Public evidence provides a concrete example of how the company integrates third-party software platforms to enforce quality control and streamline compliance on the factory floor. At the VIDAR manufacturing operations in Syracuse, New York, the company transitioned from a fragmented, paper-based Quality Management System (QMS) to a digital SaaS platform provided by a vendor named 1factory.³¹

The operational problem solved by this vendor integration was the slow retrieval of production documentation and the heavy administrative burden of audit preparation, which previously consumed days of engineering and quality staff time.³⁸ By deploying the 1factory QMS, the VIDAR facility digitized its incoming quality control (IQC), first article inspections (FAI), auto-ballooning, and supplier corrective action requests (SCAR).³⁹

The implementation resulted in measurable business impacts: audit preparation time was reduced by 83 percent (from three days to four hours), document retrieval time plummeted from 15 minutes of searching to under one minute, and supplier corrective action closure time dropped by 70 percent.³⁸ The vendor platform utilizes AWS GovCloud and supports ITAR and CMMC compliance, positioning the VIDAR facility to achieve ISO 9001 certification by establishing standardized, auditable quality processes.³⁹

Assessment:

The evidence supports vendor-supported operational deployment of digital quality management tools. The company is modernizing its factory-floor compliance and documentation workflows by buying and integrating specialized SaaS platforms rather than building internal quality management software from scratch. The measurable outcomes achieved through the 1factory integration demonstrate a strong, successful investment in operational efficiency, yielding immediate reductions in administrative overhead, accelerating compliance tracking, and facilitating ISO certification.

Agentic AI systems for managed cybersecurity operations

Uploaded-document evidence:

The annual report explicitly discloses the company's cybersecurity risk management posture and the technologies deployed to secure its digital infrastructure.¹ The filing states that ITT maintains a 24/7/365 managed security operations center (SOC) responsible for continuously monitoring the IT environment for anomalous and potentially malicious activity.¹ Crucially, the filing confirms that this managed service includes "agentic-AI capabilities" designed to more quickly identify and respond to cyber threats, proactively taking steps to contain the spread of incidents.¹ The company also deploys artificial intelligence-based threat detection technology strategically across the enterprise.¹

The filing outlines the governance structure established for these advanced technologies, noting that the company has formed a GenAI Governance Committee to review GenAI use cases, address bias, privacy, and ethical concerns, and restrict usage to approved enterprise-level tools.¹ The company explicitly prohibits the use of public versions of common AI tools with sensitive information.¹

Public-source evidence:

No direct public evidence found for the specific proprietary mechanisms or specific vendors

powering the agentic-AI SOC capabilities beyond the disclosures in the official SEC filings.
Assessment:

The evidence supports vendor-supported operational deployment of agentic AI systems within the cybersecurity domain. Because the annual report describes the SOC as a "managed service" utilizing agentic-AI, the capability is likely mediated by a third-party managed security service provider (MSSP) or a commercial cybersecurity vendor platform rather than an internally developed, proprietary autonomous AI system. The operational problem solved is the rapid identification, triage, and containment of evolving cyber threats, including those generated by adversaries using AI. The establishment of a GenAI Governance Committee confirms that the company has reached a level of maturity in its digital operations that requires formalized risk management policies for generative technologies across the workforce.

SECTION 3 — Talent, teams, and operating model

Uploaded-document evidence:

The uploaded hiring dataset reveals a highly targeted, low-volume, and geographically dispersed approach to acquiring AI, data, and software capabilities.¹ Out of 2,783 observed job postings in the dataset, only 14 were identified as AI-core roles, indicating that specialized AI talent acquisition represents a very small, focused fraction of overall corporate hiring (approximately 0.5 percent).¹ The temporal trend shows a gradual increase in AI capability building, moving from zero AI-core postings in 2023, to 5 in 2024, and peaking at 8 in 2025.¹

Geography	Total Observed Postings	AI-Core Postings	AI Intensity (%)
United States (US)	1639	2	0.12%
Italy (IT)	216	5	2.31%
Greece (GR)	104	7	6.73%
Mexico (MX)	179	0	0.00%

The hiring data points to specific business areas where capability building is occurring. "IT and Data" accounts for the vast majority of the AI-core postings (9 roles), followed by "Materials Research" (3 roles) and "Manufacturing Operations" (2 roles).¹

Geographically, the dataset shows significant hiring concentration outside of the United States. While the US represents the largest overall posting base (1,639 total postings), it accounts for only two AI-core postings (0.12 percent AI intensity).¹ Conversely, Greece exhibits the highest AI intensity, with 7 AI-core postings out of 104 total postings (6.73 percent).¹ Italy also shows relevant capability building, with 5 AI-core postings out of 216 total (2.31 percent).¹

Capability Family	Count	Business Area Focus
AI / ML modeling	11	IT and Data (6), Materials Research (3), Manufacturing (2)
LLM / GenAI apps	3	IT and Data (3)

The seniority mix for the 14 AI-core roles is relatively balanced, comprising 5 junior, 5 mid-level, and 4 senior positions.¹ The dataset does not show evidence of mass hiring for internal foundation model training; rather, the capability families sought are heavily skewed toward applied AI/ML modeling (11 roles) and LLM/GenAI applications (3 roles).¹

Public-source evidence:

Public evidence clarifies the organizational structure driving these geographical hiring concentrations. The concentration of IT, software, and GenAI hiring in Greece is directly tied to the company's "Tech Hub" located in Athens.¹⁸ This centralized hub employs over 80 professionals, including developers, designers, and project managers, who act as an internal software agency driving digital transformation across the global enterprise.¹⁸ The Athens team specifically owns the development of ePrism, the company's core CPQ and order management software.¹⁸

The hiring concentration in Italy is tethered to the company's physical R&D infrastructure. The Motion Technologies segment operates its global headquarters and a primary research and development center in Barge, Italy, alongside advanced manufacturing facilities in Termoli.⁴³ The AI/ML modeling roles identified in the materials research sector are integrated into the UniTO-ITT Joint Lab, a collaborative academic partnership located in Turin and Barge.⁸

Furthermore, the company's operating model relies heavily on external vendors and partners to supply advanced digital capabilities for its commercial products and factory floors. Rather than building large internal software teams to develop predictive maintenance algorithms, the company partners with Symphony AzimaAI for the i-ALERT diagnostic logic.²⁶ Similarly, the company partners with ABB for the hardware platforms underlying the PumpSmart drives, and with 1factory for its manufacturing QMS.³⁴

Assessment:

The combined evidence suggests an operating model that utilizes specialized, localized centers of excellence combined with strategic vendor partnerships. Internal software development and enterprise GenAI capability building are centralized in the Athens Tech Hub, allowing the company to consolidate its IT and data talent in a specific European geography, which explains the high AI hiring intensity in Greece. Materials science and manufacturing AI exploration are localized in Italy, tightly coupled with physical R&D infrastructure and academic partnerships. For commercial digital products, the company operates a hybrid model. It maintains internal

ownership of embedded control logic (e.g., PumpSmart, VIDAR) but relies on third-party vendors to supply the underlying hardware components and complex cloud-based machine learning algorithms (e.g., Symphony AzimaAI for i-ALERT). This approach limits the need for massive internal AI engineering headcount, which aligns with the relatively low volume of AI-core job postings observed in the dataset. The evidence indicates that ITT is a pragmatic adopter of digital technology, favoring targeted internal capability building for enterprise workflows while acquiring or licensing mature software for product commercialization and manufacturing compliance. The uploaded hiring dataset does not show evidence that the company is replacing its core engineering workforce with AI roles, but rather augmenting its traditional teams with localized software expertise.

SECTION 4 — What the evidence implies for investment priorities and competitor monitoring

Based on the synthesis of financial disclosures, hiring data, and public evidence, ITT is executing a highly focused digital strategy that treats software and AI as enabling components for its traditional hardware businesses, rather than attempting to pivot into a standalone software company. The evidence points to four distinct investment priorities that carry strategic implications for competitors in the flow control, automotive friction, and industrial components markets.

Priority 1: Augmenting fluid and flow hardware with embedded intelligence and vendor-backed diagnostics

The company is heavily prioritizing investments that embed digital control systems and connectivity directly into its industrial equipment to lower the total cost of ownership for its customers and shift maintenance from reactive to proactive.

- **Evidence base:** The launch and production deployment of the VIDAR variable-speed smart motor ¹; the deployment of proprietary PumpSmart control logic on ABB hardware drives ³⁴; the i-ALERT3 sensor ecosystem utilizing Symphony AzimaAI algorithms for automated cloud-based diagnostics.²⁴
- **Company objectives:** The company aims to transition passive rotating equipment into active, digitally monitored systems. By embedding software into motors and pumps, ITT seeks to reduce energy consumption, eliminate mechanical controls, and prevent catastrophic failures through predictive maintenance and sensorless flow calculations.
- **What is known:** ITT successfully manufactures edge hardware (sensors, variable frequency drives) and develops proprietary pump-control logic internally. For complex vibration analysis and machine health diagnostics in the cloud, ITT integrates third-party algorithms rather than building proprietary foundation models.
- **What remains uncertain:** It is unclear what percentage of total Industrial Process segment revenue is derived from recurring SaaS subscriptions or software licenses associated with the i-ALERT and VIDAR platforms, as these digital metrics are embedded within hardware sales in the financial filings.
- **Competitor implication:** Competitors in the industrial pump and flow control markets

should note that ITT is accelerating its digital offerings by partnering with established AI vendors (like AzimaAI). Because ITT is not building these predictive algorithms internally from scratch, competitors have the opportunity to license similar capabilities from the broader B2B AI market to achieve parity. However, ITT's competitive advantage lies in its massive installed hardware base and its ability to seamlessly integrate edge sensors (i-ALERT3) with legacy equipment. Competitors must focus on the physical integration, ruggedness, and user interface of their IoT ecosystems to remain competitive, rather than solely competing on algorithmic accuracy.

Priority 2: Accelerating friction materials research through computational modeling

The company is prioritizing funding for academic partnerships and internal machine learning capabilities to accelerate the development of advanced friction materials and reduce reliance on expensive physical prototyping.

- **Evidence base:** The 50 million Euro capital investment in the Termoli and Barge R&D and production facilities³; the operation of the UniTO-ITT Joint Lab⁹; the publication of scientific research demonstrating the use of machine learning to predict and control the morphology of TiO₂ nanoparticles⁸; the exploration of AI to reduce fuel use and particulate matter in physical brake pad testing.¹²
- **Company objectives:** The company seeks to maintain its leadership in high-performance brake pads by reducing R&D cycle times. By predicting chemical synthesis outcomes digitally, the company can bring complex, environmentally compliant friction materials (such as the Geo-Pad) to market faster and with lower physical overhead.
- **What is known:** The company employs AI/ML modeling roles in Italy specifically for materials research. The ML models developed at the Joint Lab have successfully demonstrated the ability to reverse-engineer synthesis parameters to achieve specific nanoparticle shapes and sizes. The company is actively bringing new formulations (Geo-Pad) to OEM trials.
- **What remains uncertain:** The extent to which these machine learning models have been scaled beyond isolated R&D projects and fully integrated into the standard global manufacturing pipeline remains unquantified by public evidence.
- **Competitor implication:** Competitors in the automotive and rail friction markets must recognize that relying solely on physical prototyping is becoming a competitive disadvantage. ITT's ability to simulate and predict material performance digitally will likely yield faster compliance with strict environmental regulations (such as Euro 7 emissions standards) and faster adaptation to electric vehicle braking requirements. Competitors who do not invest in computational materials science risk longer product development cycles, higher physical testing costs, and delayed time-to-market.

Priority 3: Modernizing quoting and enterprise workflows via generative AI and internal tech hubs

The company is prioritizing the centralization of its enterprise software development to build intelligent, generative tools that reduce administrative friction in its commercial sales operations.

- **Evidence base:** The establishment and staffing of the 80-person Athens Tech Hub ¹⁸; the internal development of the ePrism CPQ and order management platform ¹⁸; the active hiring of Senior AI/ML engineers in Greece to deploy Azure OpenAI, Copilot Studio, and RAG architectures ²²; the deployment of the 1factory QMS software at the VIDAR facility to digitize compliance. ³⁸
- **Company objectives:** ITT is attempting to streamline complex B2B sales cycles, automate document data extraction, and improve quality control compliance on the factory floor. By integrating GenAI into ePrism, the company aims to reduce the time required to configure highly engineered products and generate accurate quotations.
- **What is known:** The company utilizes a Microsoft Azure technology stack for its GenAI exploration. The Athens hub serves as the central engine for this internal software development. The company has formally established a GenAI Governance Committee to manage the security and data integrity risks of these deployments.
- **What remains uncertain:** The hiring data indicates capability building and intent, but public evidence does not yet confirm that RAG or agentic systems within ePrism are fully operational or scaled across the entire global sales force. The measurable ROI of the Azure OpenAI integration is currently undisclosed.
- **Competitor implication:** Competitors should expect ITT to execute faster, more accurate sales cycles as ePrism's GenAI capabilities mature. The ability to automate complex industrial quoting using LLMs provides a significant operational margin advantage by reducing the administrative load on sales engineers. Competitors should audit their own CPQ processes; relying on manual configuration or disparate spreadsheets for engineered-to-order industrial products will likely become a distinct commercial disadvantage as digitally augmented workflows become the industry standard.

Priority 4: Scaling industrial capabilities through inorganic M&A

The company continues to prioritize large-scale acquisitions to rapidly acquire engineering talent, manufacturing capacity, and adjacent product lines, utilizing its strong balance sheet to drive growth.

- **Evidence base:** The pending acquisition of SPX FLOW for \$4.775 billion ¹; the issuance of \$1.3 billion in equity and \$2.875 billion in debt commitments to fund the transaction ¹; the completed 2024 acquisitions of kSARIA and Svanehoj for a combined \$867.7 million. ¹
- **Company objectives:** The company aims to reshape its portfolio toward high-growth, high-margin flow and interconnect markets while reducing its exposure to legacy automotive components (as evidenced by the Wolverine divestiture).
- **What is known:** The SPX FLOW acquisition will add 3,800 employees and significant footprint in food, beverage, personal care, and chemical markets. The company relies heavily on commercial paper and term loans to finance these acquisitions, leveraging its

investment-grade credit ratings.

- **What remains uncertain:** The specific software or digital synergies that will be realized from integrating SPX FLOW's technology stack with ITT's existing IT infrastructure are not yet detailed, and the integration process introduces operational risks.
- **Competitor implication:** Competitors must monitor ITT's rapidly expanding scale in the flow control and aerospace interconnect markets. The integration of SPX FLOW will likely create cross-selling opportunities for ITT's digital platforms, such as expanding the reach of i-ALERT diagnostics into SPX FLOW's installed base. Competitors may face increased pricing pressure and a more consolidated market landscape as ITT leverages its expanded global footprint and digital tools across a broader portfolio.
